Anderson, PhD; on behalf of the Stroke123 Investigators and AuSCR Consortium

Background and Purpose—Hospital uptake of evidence-based stroke care is variable. We aimed to determine the impact of a multicomponent program involving financial incentives and quality improvement interventions, on stroke care processes.

Methods—A prospective study of interventions to improve clinical care quality indicators at 19 hospitals in Queensland, Australia, during 2010 to 2015, compared with historical controls and 23 other Australian hospitals. After baseline routine audit and feedback (control phase, 30 months), interventions involving financial incentives (21 months) and then addition of externally facilitated quality improvement workshops with action plan development (9 months) were implemented. Postintervention phase was 13 months. Data were obtained for the analysis from a previous continuous audit in Queensland and subsequently the Australian Stroke Clinical Registry. Primary outcome: change in median composite score for adherence to ≤8 indicators. Secondary outcomes: change in adherence to self-selected indicators addressed in action plans and 4 national indicators compared with other Australian hospitals. Multivariable analyses with adjustment for clustered data.

Results—There were 17 502 patients from the intervention sites (median age, 74 years; 46% women) and 20 484 patients from other Australian hospitals. Patient characteristics were similar between groups. There was an 18% improvement in the primary outcome across the study periods (95% CI, 12%–24%). The largest improvement was following introduction of financial incentives (14%; 95% CI, 8%–20%), while indicators addressed in action plans provided an 8% improvement (95% CI, 1%–17%). The national score (4 indicators) improved by 17% (95% CI, 13%–20%) versus 0% change in other Australian hospitals (95% CI, −0.03 to 0.03). Access to stroke units improved more in Queensland than in other Australian hospitals (P<0.001).

Conclusions—The quality improvement interventions significantly improved clinical practice. The findings were primarily driven by financial incentives, but were also contributed to by the externally facilitated, quality improvement workshops. Assessment in other regions is warranted. (Stroke. 2019;50:00-00. DOI: 10.1161/STROKEAHA.118.023075.)

Key Words: health services ★ historically controlled study ★ humans ★ quality of health care ★ reimbursement, incentive ★ stroke

Improving access to evidence-based care, including specialized stroke units, intravenous thrombolysis and thrombectomy in eligible patients with acute ischemic stroke, and medications for secondary prevention, is recommended for optimal stroke outcomes. Yet many patients fail to receive these therapies, even in well-resourced settings. Various strategies have been proposed to reduce evidence-practice gaps. These include audit and feedback, education and training, reimbursement, and financial incentives. While single strategies have been shown to improve care, combination of different strategies may be more effective. The current study assessed the impact of a multicomponent program involving financial incentives and quality improvement interventions, on stroke care processes.

The authors conducted a multicenter, prospective, controlled, before-and-after study at 19 hospitals in Queensland, Australia, during 2010 to 2015. The study was compared with historical controls and 23 other Australian hospitals. The intervention consisted of baseline routine audit and feedback (control phase, 30 months), followed by interventions involving financial incentives (21 months) and then addition of externally facilitated quality improvement workshops with action plan development (9 months). The postintervention phase was 13 months. Data were obtained for the analysis from a previous continuous audit in Queensland and subsequently the Australian Stroke Clinical Registry.

The primary outcome was the change in median composite score for adherence to ≤8 indicators. Secondary outcomes included change in adherence to self-selected indicators addressed in action plans and 4 national indicators compared with other Australian hospitals. Multivariable analyses with adjustment for clustered data were used to determine the impact of the interventions.

The study included 17,502 patients from the intervention sites (median age, 74 years; 46% women) and 20,484 patients from other Australian hospitals. Patient characteristics were similar between groups. There was an 18% improvement in the primary outcome across the study periods (95% CI, 12%–24%). The largest improvement was following introduction of financial incentives (14%; 95% CI, 8%–20%), while indicators addressed in action plans provided an 8% improvement (95% CI, 1%–17%). The national score (4 indicators) improved by 17% (95% CI, 13%–20%) versus 0% change in other Australian hospitals (95% CI, −0.03 to 0.03). Access to stroke units improved more in Queensland than in other Australian hospitals (P<0.001).

The study concluded that the quality improvement interventions significantly improved clinical practice. The findings were primarily driven by financial incentives, but were also contributed to by the externally facilitated, quality improvement workshops. Assessment in other regions is warranted.

The study was presented at the European Stroke Organisation Conference, Gothenburg, Sweden, May 16–18, 2018. and the influence of key opinion leaders and professional groups, often with local tailoring and used in combination.  

However, few studies to evaluate these multicomponent strategies that target clinician behavior within hospitals have been undertaken for stroke. Examples include the Get-With-The-Guidelines—Stroke and Quality in Acute Stroke Care trial in Australia. There is also a lack of evidence for the use of financial incentives to improve stroke care.  

Within Australia, there are 2 main standard quality improvement activities in hospitals. These include the biennial national audit program (since 2007) and the Australian Stroke Clinical Registry (AuSCR; established in 2009), which has fewer clinical processes than the audit but is collected on all admitted patients and has a 90-day outcome survey. Feedback to hospitals from these programs includes sending personalized benchmarked reports. Within Queensland, additional strategies have included introduction of financial incentives and use of external quality improvement officers to help local teams develop action plans to address evidence-practice gaps (StrokeLink program). We undertook a project (Stroke123) to assess the real-world effectiveness of the new Queensland quality improvement initiatives against a background of standard activities. The primary hypothesis being tested was that Queensland hospitals eligible for financial incentives and participating in an enhanced StrokeLink program could demonstrate greater adherence to a defined set of acute stroke clinical indicators compared with a historical control period and to other hospitals in Australia.  

**Methods**

**Design**

Details of the Stroke123 study design are outlined in detail elsewhere. In brief, a prospective, multicenter, before-and-after study design was used to compare performance across hospitals according to Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines. We approached all 23 public hospitals in Queensland, which admitted ≥100 patients (age, ≥18 years) with acute stroke or transient ischemic attack per annum. These hospitals all contributed data to AuSCR and previous audit programs. Ethics approvals were obtained from Monash University (2013-2058-1867) and Metro South Human Research Ethics Committee (HREC/13/QPAH/31) being the lead ethics committee for the Queensland hospitals. Individual informed consent was not required because this was secondary use of deidentified data. The data underlying the findings are available from the corresponding author on reasonable request.  

**Interventions**

There were 2 intervention components to change practice: financial incentives and the enhanced StrokeLink program. The financial incentive program implemented from 2012 was developed to provide an incentive payment to increase access to stroke units according to the published Statistical Analysis Plan (Figure). In this pragmatic real-world study, stroke clinical indicator data were from 2 comparable sources. Historical data from Queensland collected using similar methods to AuSCR (ie, minimum set of variables on all admitted patients) before 2012 were matched to the AuSCR, and the data quality was found to be similar (Table III in the online-only Data Supplement). The main difference was lack of 1 variable in the historical Queensland dataset: care plan outlining postdischarge care in the community developed with the team and the patient. Therefore, our analysis using primary composite score either included 7 (T) or 8 clinical indicators (T,T). To assess for the possibility that the results may have been influenced by 1 clinical indicator missing from the historical period, we conducted a sensitivity analysis excluding use of a discharge care plan from the composite score. The action plan score analysis was limited to 14 hospitals with nominated indicators in their action plans (Table III in the online-only Data Supplement). Because of the skewed distribution of composite score data, median (interquartile limits) for all composite scores in each time period, adjusted for clustering by hospital. Multilevel random-effects logistic regression analysis was used to measure change in adherence to individual clinical indicators by time period at the hospital level. Models were also generated with a test of interaction (time periods x location, ie, Queensland versus other Australian hospitals) but without adjustment for patient characteristics as all quality indicators were universally applicable to eligible patients. Secondary analyses included
adjustment for available data on patient characteristics (age, sex, stroke severity [ability to walk on admission], and stroke type) because patient-level factors may explain ≤2% of variability in care. 16 Significance was 2 sided (α < 0.05). All statistical analyses were undertaken using Intercooled STATA 12.1 for Windows (Statcorp, College Station; 2014).

Results

The study included 19 of the 23 eligible Queensland hospitals (83%) and 23 others located elsewhere in Australia (Figure). Across the 19 Queensland hospitals, a total of 17,502 patients were evaluated across the time periods, with 4781 in T0 and 3815 in T3 for the primary analysis. Correspondingly, there were 20,484 patients included across the 23 non-Queensland hospitals during all study periods, including 5903 in T0 and 5188 in T3 (Figure). Patient characteristics were similar between comparator periods and between Queensland and non-Queensland hospitals (Table IV in the online-only Data Supplement).

Table 1 shows that the median primary composite score increased from 0.57 (T0) to 0.75 (T3; P < 0.001). In adjusted analyses, there was a 15% improvement in median scores after introduction of financial incentives and this increased to 18% during the full intervention period. These trends attenuated and became nonsignificant in the sensitivity analysis excluding use of a discharge care plan indicator from T1 to T3 (Table V in the online-only Data Supplement). In secondary outcome analyses limited to those clinical indicators specifically nominated by participating hospitals (n=14), action plan score medians increased by 5% after introduction of financial incentives (T0 compared with T1, nonsignificant) and 8% during the whole intervention period (T0 compared with T3, P < 0.05; Table 2). Finally, limiting the analysis to the 4 common national indicators, the national score increased by 17% (95% CI, 13%–20%) at participating Queensland hospitals but was stable across non-Queensland hospitals (0%; 95% CI, –3% to 3%; Table 3). Results were consistent in supplementary analyses adjusting for patient characteristics (Table VI in the online-only Data Supplement). In both intervention hospitals in Queensland and nonintervention hospitals elsewhere, the trends were for improved individual patient indicators.
during the study period (Table 4; Table VII in the online-only Data Supplement).

Discussion

In this multicenter observational study, substantial improvements were evident across several clinical indicators of hospital performance following implementation of a multicomponent quality improvement program (ie, financial incentives and feeding back data to hospital clinicians through StrokeLink). Improvement was the greatest after a financial incentive to improve stroke unit access was introduced (14% improvement from T₀ to T₁). These data suggest that multicomponent and complementary interventions are more effective than single-component interventions to improve systems of stroke care. These findings are in contrast to a recent review in which the authors concluded that there was no compelling evidence that multicomponent interventions were more effective than single-component intervention.¹⁸

Our overall finding of an 18% improvement in the primary composite score is large and at the upper limit of the treatment effect for other types of quality improvement interventions assessed in randomized trials.²⁻²° However, it appears valid because this improvement occurred against a background of stable performance where conventional passive audit and feedback processes were used in hospitals elsewhere in Australia during the study periods (national score). We acknowledge that baseline adherence to performance indicators in non-Queensland hospitals was larger than in Queensland hospitals (Table VII in the online-only Data Supplement) and may have influenced the overall comparisons if there were ceiling effects. However, this is unlikely because performance across non-Queensland hospitals remained below achievable benchmarks of top performing hospitals based on 2015 AuSCR data (ranging from 5% below benchmarks for intravenous thrombolysis and 31% below for discharge care plans).²⁹ Overall, the comparator hospitals had small improvements across several individual clinical indicators that were consistent with systematic review evidence of audit and feedback interventions (pooled median 4.3% effect size).³⁰ Reported effects of other hospital-based pay-for-performance interventions have been variable,³¹ ranging from no effect³² to a 4% to 22% improvement in programs for acute coronary syndrome, heart failure, and pneumonia.³³ Success of the Queensland financial incentive program is consistent with the evidence for an implementation strategy led by clinical leaders with support by government in a setting of low baseline performance.³⁴ Although funding mechanisms differ across health systems, the principles of the Queensland financial incentives provide a basis for other countries to establish similar pay-for-performance schemes for increasing access to stroke units.

The association between stroke unit care and patient outcome is undisputed³⁵ and is the cornerstone for providing best-practice care in hospitals. The initial targeting of stroke unit care with financial incentives was associated with concurrent improvements in adherence to some (ie, thrombolysis for acute ischemic stroke and early mobilization), but not all, measured clinical indicators. This evidence is consistent with other research, whereby stroke units are associated with greater adherence to evidence-based processes of care than other models of care.¹¹,²⁴,²⁵ Strategies to improve clinical practice should account for local factors that might inhibit quality improvement.²⁶ In this study, the use of the externally facilitated enhanced StrokeLink program was associated with a nonstatistically

National score is a composite of adherence to 4 indicators: receipt of stroke unit care, thrombolysis in acute ischemic stroke, prescription of antihypertensive medication at discharge, and use of a discharge care plan. AuSCR indicates Australian Stroke Clinical Registry.
*Only uses AuSCR data from hospitals during these equivalent time periods not located in Queensland.
†Dependent variable, composite score; independent variable, intervention phase; adjusted for patient clustering by hospital.
significant additive increase in both the primary composite score (4%) and action plan scores (3%) after introduction of financial incentives—an effect size that is consistent with published findings of comparable interventions.26 The other reported system-wide quality improvement intervention based on audit and feedback in stroke is the Get-With-The-Guidelines program.7 This intervention was similar to our baseline quality improvement interventions, but more intensive (quarterly workshops, more education), and did not include feedback of patient-level outcomes. These authors report a composite score increase of 10.5% during 5 years with an annualized increase in the odds of receiving measures in their composite score of 1.18.3 Specific novel components in our intervention that may have contributed to our somewhat better improvement included feedback of long-term patient outcomes and ongoing support provided to hospitals via email and telephone. Because many countries have national registries for monitoring stroke care including longer term patient outcomes,47 our approach to audit and feedback could be replicated whereby feedback of long-term outcomes is incorporated, where feasible.

Strengths of our study include being multicentered, the large sample sizes, and continuous longitudinal data. Only 4 public hospitals in Queensland were excluded because they did not participate in either AuSCR or the enhanced StrokeLink program. Therefore, the included hospitals represented different service levels from small regional to large comprehensive stroke units, strengthening the generalizability of our results. We used historical controls in Queensland and contemporaneous controls from other states in Australia to avoid threats to internal validity.

Limitations of our study include the lack of randomization and the inability to firmly distinguish the effects of the individual intervention components, which was not our aim. Attribution of any changes seen subsequent to an improvement intervention may be complicated by factors other than the intervention that may interfere with the system or disrupt the pattern of data.28 The temporal and additive nature of the observed associations provides confidence in the whole package, as does the lack of change in the national score in other Australian comparator hospitals. We were also conservative in our approach to not overestimate effects in our handling of missing indicator data whereby we assumed the process of care did not occur.

In conclusion, the complementary and iterative interventions tested in this real-world study, comprising financial incentives and externally facilitated feedback of registry data with action planning, led to substantial and clinically relevant improvements in best-practice care. Our interventions are readily transferable. Our study contributes important knowledge that can be used to help improve health systems and clinical services for stroke. The individual components and the combined quality improvement intervention deserve further study and application in other regions and countries.

**Acknowledgments**

We thank the hospital clinicians and patients who contributed data to the Australian Stroke Clinical Registry (AuSCR). We are also grateful to the program facilitators, staff from the AuSCR, the George Institute for Global Health and the Florey Institute of Neuroscience and Mental Health, the Stroke Foundation and members of the AuSCR Management and Steering Committees for their support related to this project and AuSCR (see Acknowledgments in the online-only Data Supplement for coinvestigators and other contributors to the Stroke123 project or AuSCR). We are grateful to Prof Leonid Churilov for his advice on the statistical analysis.

**Sources of Funding**

The Stroke123 project was supported by the National Health and Medical Research Council (NHMRC) partnership grant 1034415, cofounded by Queensland Health, Monash University, and the Stroke Foundation of Australia. Financial incentives were funded by Queensland Health through their Quality Improvement Payment Program. The following authors received research fellowship support from the NHMRC: Prof Cadilhac (1063761 cofunded Heart Foundation), Dr Andrew (1072053), Prof Anderson (1081356), Dr C. Levi (1043913), A/Prof Lannin (1112158), Prof Thrift (1042600), and Dr Kilkenny (1109426). The Australian Stroke Clinical Registry was supported by grants from the NHMRC (1034415), Monash University, Queensland Health, Victorian Department of Health and Human Services, Tasmanian government the Stroke Foundation, Allergan Australia, Ipsen, Boehringer Ingelheim, and consumer donations.
